Software Testing and Validation A.A. 2022/2023 Corso di Laurea in Informatica

**Basic Notions** 

Igor Melatti

#### Università degli Studi dell'Aquila

Dipartimento di Ingegneria e Scienze dell'Informazione e Matematica

### General Info for This Class

- Software Testing and Verification is an elective course for the Informatica Bachelor Degree
- Lecturer: Igor Melatti
- Where to find these slides and more:
  - https://igormelatti.github.io/sw\_test\_val/ 20222023/index.html (Italian)
  - https://igormelatti.github.io/sw\_test\_val/ 20222023/index\_eng.html (English)
  - also on MS Teams: "DT0758: Software Testing and Validation 2022/23", code 098n9tu
- 2 classes every week, 2 hours per class

#### Rules for Exams

- Each exam has a written part (50% of mark) and a project/paper (50% of mark)
  - each student may choose if making a project or reviewing a paper
  - teams of at most 2 students are allowed for projects
- Written exam will be a mix of open and closed questions on the whole exam program
- Project/paper may be discussed only after having passed the written exam
  - however, pre-evaluation is possible

### Rules for Exams

- Project: perform testing and validation of a given software
  - each team may choose one among the ones selected by lecturer
  - or may propose one (but wait for lecturer approval!)
  - each team will have to discuss its project with slides
- Paper: read a conference or journal paper and present it with slides
  - each student may choose one among the ones selected by lecturer
  - or may propose one (but wait for lecturer approval!)

- Dates back to computer science origins
  - of course, not only in computer science
- Let us focus on software
- Only in some few cases it is possible to generate (synthesize) a correct-by-construction program starting from (formal) requirements
- Otherwise, the verification problem would not exist, at least not in its current form

#### Utopia!

- Suppose you want to write a software fulfilling some given requirements
  - given an array A, sort A in a non-decreasing way
  - given a graph G = (V, E) and two nodes u, v ∈ V, decide if there exists a path from u to v
  - build the data base for a library
  - write a program able to manage an airport
  - etc.
- Q Let us try to write the corresponding requirements
  - $\forall 1 \leq i \leq n-1 \ A[i] \leq A[i+1]$
  - $\exists u_1, \ldots, u_n$  s.t.

 $u_1 = u \wedge u_n = v \wedge \forall 1 \leq i \leq n-1 (u_i, u_{i+1}) \in E?$ 

 It is possible also for the remaining cases, though it is more complicated

#### Utopia!

- Suppose you have an automatic program synthesizer (generator)
  - a special program which takes *requirements* as input
    - must be described in some *formal* way, i.e., using an unambiguous mathematical language
  - ... and outputs a correct-by-construction program which fulfills the input requirements

## Utopia!

- All efforts are in making the program generator correct, efficient and effective
- It outputs correct-by-construction programs
  - if I say "give me a program sorting arrays", then I obtain a program which *never* fails
  - i.e., given any array (input instance), it outputs always the correct sorted array (corresponding output)

#### Instead, the Reality

DiSIM Dipartimento di Ingegneria e Scienze dell'Informazione e Matematica

#### Instead, the Reality

- Do you need to build a software? then, you will have to do it ad hoc
  - *totally* general approaches to build program generators cannot exist
  - it is easy to see that building a program generator is an undecidable problem
- Of course, you can rely on libraries, methodologies, etc, but...
- ... there is no guarantee that the starting requirements are met by the final software
  - e.g., if you implement an iterative program to sort arrays, but you forget to increment the index, the starting requirements will not be met
  - more subtle errors may be very difficult to find

- So you need a verification phase
  - for simple cases like sorting, it is sufficient to perform it in the end
  - for more complex cases, verification must be performed also during developing phase
- Verification goal is to find errors, if any
  - for our pruposes, an error is a violation of the requirements
  - some requirements are present since the beginning, some other may add up later

- Software Engineers are well aware of the problem
- All software design processes include one or more verification phases
  - though it may be simply called *test* o *testing*

- Software Engineers are well aware of the problem
- All software design processes include one or more verification phases
  - though it may be simply called *test* o *testing*

- Software Engineers are well aware of the problem
- All software design processes include one or more verification phases
  - though it may be simply called *test* o *testing*

- Software Engineers are well aware of the problem
- All software design processes include one or more verification phases
  - though it may be simply called *test* o *testing*

## Systems Verification

- We have been speaking of software, but all we said holds for any computer-based system
- Hardware
  - digital circuits
  - microprocessors
- Embedded Systems
  - tiny *dedicated* computer inside bigger systems
  - typically, either controllers or monitors
  - cars (ABS, ESC/ESP...), generic means of transportation, domestic electrical appliances (fridges, TVs, ...)
  - errors could be in hardware, software, both, or in the "communication" (interface) between hardware and software

## Systems Verification

Summing up:

- start from requirements
- Output of the second second
  - you may "complicate" such steps at wish
- verify that the current solution fulfills the starting requirements
  - you may need to change the requirements (they could be wrong too, or they may have been changed)
  - recall that verification may also be done during the intermediate developing steps

## Validation

- Verification and validation are often used as synonyms
- However, there is an important distinction between the two terms
  - validation involves final users "expectations"
  - verification is performed only keeping in mind the software requirements already collected
  - verification does not care whether requirements are what users want or not
- Validation is "did we built the right system?"  $\rightarrow$  useful system
- $\bullet$  Verification is "did we built the system right?"  $\rightarrow$  dependable system

- Requirements analysis vs. requirements specifications
  - requirements analysis: what (we understood that) the users want
  - requirements specification: the solution we propose for the requirements analysis
- Validation is about checking requirements anaysis
  - more focused on the overall requirements and the final code
- Verification is about checking requirements specifications
  - often with intermediate steps
- In this course, we will mainly focus on verification
  - though also validation will be treated

#### Validation and Verification

#### How Verification is Performed

- Method number 1: Testing
  - you have the actual system (or a part of it)
  - 9 you feed it with predetermined inputs
  - you check if outputs are the expected ones
    - "expected" w.r.t. the requirements
  - if there is one output different from the expected one, then we have an error
  - you correct it and start over again
- Method number 1 bis: Simulation
  - instead of using the actual system, you have a *(software)* simulator
  - especiall useful for hardware or for physical parts
  - if you want to do testing on hardware, you need to actually build it, which may be expensive

# An approximate answer BUG HUNTING: Testing + Simulation

- Both testing and simulation may be performed in refined ways
- In fact, the *testing plan* (the predetermined sequence of inputs) may be computed using dedicated algorithms so that *coverage* is maximized
  - we will get back soon on this concept
- This is the most challenging and important step for such techniques

## Testing and Simulation: Pro and Cons

#### Pro

- (Relatively) easy to implement
  - easier than the other methods we will consider here
- Largely used in industry
  - in most cases, testing and/or simulation are the *only* verification methods used

#### Cons

- They can prove that a system *has* errors, but cannot prove that a system *does not have* errors
- Cannot be used to prove generic formal properties
- The coverage of the "input space" is low
- Errors are frequently detected when it is too tate

They can prove that a system *has* errors, but cannot prove that a system *does not have* errors

- If an error is detected, then the system must be corrected, happy to have discovered it
- Otherwise, we cannot conclude anything
- That is, we cannot say that the system is error-free
- In fact, having not be able to spot errors does not imply that there are no errors

Cannot be used to prove generic formal properties

- This is a consequence of the previous slide
- As an example: in an operating system, is it true that mutual exclusion is enforced for 2 given processes?
- In order to test such a property you would have to modify the system itself
  - so that the output contains something like "propriety violated" or "property ok"
- But even in this case, we cannot draw a formal statement on the validity of the property
- Again, not finding a violation does not imply there are no violations

The coverage of the "input space" is low

- A successful testing phase should consider "all what may happen" to the system in a real-world environment
- This would need too much tests or simulations

• The *n* in the figure may easily be  $10^6$  and more; outputs must also be checked

The coverage of the "input space" is low

- This also has another bad consequence
- Testing and simulation find the "easy" errors
  - the most frequent ones
  - i.e., those that are caused by many (different) input sequences
- Instead, corner cases usually go undetected
  - i.e., errors that are caused by a few (or even single) input sequences are usually not found

Errors are frequently detected when it is too late

• This is a consequence of the previous point: you need many tests to get a reasonable coverage and discover possible corner cases

- To solve the above underlined problems, we should consider *all* inputs
- That is, al possible system evolutions
  - of course, testing and simulation only consider *some* evolutions: those "activated" by inputs chosen by the testing plan in use
- A possible way to do this is to prove a dedicated theorem, stating that the system is correct for all inputs
- For sorting, this could be done (and it is actually done in Algorithms textbooks...)
- For other cases (e.g., microprocessor design), it would be too difficult or time consuming
- Thus, techniques of formal verification have been developed

- A set of (heterogeneous) techniques which make possible the impossible
- That is, algorithms able to generate and analyze *all* system evolutions
  - so, they provide a *mathematical certification* of correctness (not achievable with testing/simulation)
  - also for generic properties, like mutual exclusion
- Actually, the problem of verifying a given system w.r.t. a given property is *undecidable* 
  - the property to be verified may be: is this system always terminating?
- So, there will be some (acceptable in many cases) limitations

- There are many techniques available for formal verification
- Applying any of these techniques is usually much more difficult than testing/simulation
  - both in terms of researchers and notions required
- So, why to do this?
- Because there are many cases in which testing/simulation simply *are not enough* 
  - for both economic and safety reasons

#### • Safety-critical systems: failures may affect humans

- public transport software controllers (if an automatic pilot of an airplane has a failure...)
- trains crossing
- ABS for cars
- ...
- For most of such systems, formal verification is mandatory by law
  - ESA (European Space Agency)
  - IEC (International Electrotechnical Commission)

### Is Formal Verification Useful?

#### • Mission-critical systems: failures cause huge economic losses

- automatic space probes
- logistics
- communication networks
- microprocessors
- ...
- Internal company regulations often make formal verification mandatory as well

- Also for systems which are neither safety nor mission critical: there are economic motivations to use formal verification
- Using testing/simulations, errors are eventually discovered
- The problem is that they may be found late
  - this is a consequence of the low coverage issue
- So late, that often errors are found *after* the system has been deployed, i.e., when it is already used by its final users
  - for, e.g., a *word processor*, it is annoying, but we are somewhat used to software updates to fix bugs
  - this is not always possible or easy
    - e.g., a legacy software out of support

- Hardware circuits: to "write" a circuit on silicon is the most expensive part of the developing process
- So, finding an error after having written the circuit entails a huge economic loss
- This also holds for other systems, when the developing process is lengthy
- In fact, finding a late error may cause going again through preceding developing phases
  - less competitivity on the market
  - for both being late and for augemented costs

## Is Formal Verification Useful?

- Some famous errors in safety-critical systems
  - 20/7/1969: Apollo 11, during the final descent on the Moon, the driving computer fails multiple times
    - all ok because the large support team on Earth understands the error may be ignored
  - 26/9/1983, URSS believes USA have launched 5 nuclear weapons
    - no 3rd WW only because a Russian official finds it strange there are only 5 missiles
    - all due to a software bug in recognizing false negatives
  - 1985-1987: Therac-25, computer system to treat cancer through rediations
    - many patients due to too high radiations
    - the error was afterwards tracked to a "race condition" among concurrent processes

## Is Formal Verification Useful?

#### • Some famous errors in mission-critical systems

- 1962: Mariner 1 automatic space probe (80 M\$)
  - the most expensive dash in history
  - that is, in the software, the dash sign for numbers is missing
  - resulting trajectory is completely wrong
  - the support team blows the probe to avoid it hits something on ground
- 1990: AT&T network failure
  - just one code line wrong in one telephone exchange
  - for hours, 60000 users are unable to make calls
- 1990: another space probe, Ariane 5 (500 M€)
  - overflow in converting numbers from 64 to 16 bits (!)
  - due to reuse of Ariane 4 software

#### • Some famous errors in mission-critical systems (continued)

- 1994: Intel Pentium computes wrong ansers on some floating point errors (450 M\$)
- 2006: Airbus A380 internal wires
  - errors in the software controlling wiring
  - all design process have to be restarted from scratch
  - extremely huge economic losses
- 2010: Toyota Prius ABS
  - error "glitch" in the ABS controller
  - 185,000 cars recalled for updating
  - also bad publicity

## Is Formal Verification Useful?

- A should-be-famous error in mission-critical systems: Needham-Schroeder protocol
  - public-key authentication protocol, designed in 1978
  - widespread use in many systems for decades
  - initiated a large body of work on the design and analysis of cryptographic protocols
- After 17 years of usage, an error was (manually) discovered in 1995 by Lowe
- In 1996, Lowe showed that, using formal verification, it would have been easy to immediately detect the error
  - more in detail, by using model checking
- Other examples are in https://spinroot.com/spin/success.html

# Summing Up

• Testing and simulation are the most used verification tools

- most companies (especially for software) use only these tools
- easier and cheaper to use
- at least one between testing and simulation are *always* performed
- For mission critical or safety critical systems, formal verification methods must be used
  - more difficult to be applied
  - may provide a methematical certification for the system correctness
  - only applied when budget allows it

There are two macro-categories:

Interactive methods

Automatic methods

There are two macro-categories:

- Interactive methods
  - as the name suggests, not (fully) automatic
  - human intervention is typically required
  - in this course, we do not deal with such techniques

Automatic methods

There are two macro-categories:

- Interactive methods
  - as the name suggests, not (fully) automatic
  - human intervention is typically required
  - in this course, we do not deal with such techniques
- Automatic methods
  - only human intervention is to model the system

There are two macro-categories:

- Interactive methods
  - as the name suggests, not (fully) automatic
  - human intervention is typically required
  - in this course, we do not deal with such techniques
- Automatic methods
  - only human intervention is to model the system
- There also exist hybridations among the two categories

### Interactive Methods

- Also called proof checkers, proof assistants or high-order theorem provers
- Tools which helps in building a mathematical proof of correctness for the given system and property
- Pros
  - virtually no limitation to the type of system and property to be verified
- Cons
  - highly skilled personnel is needed
  - both in mathematical logic and in deductive reasoning
  - needed to "help" tools in building the proof

- Used for projects with high budgets
- For which the automatic methods limitations are not acceptable
  - used, e.g., to prove correctness of microprocessor circuits or OS microkernels
- Some tools in this category (see https://en.wikipedia.org/wiki/Proof\_assistant):
  - HOL
  - PVS
  - Ocd Cod

## Automatic Methods

- Commonly dubbed *Model Checking*
- Model Checking software tools are called model checkers
- There are some tens model checkers developed; the most important ones are listed in https://en.wikipedia.org/ wiki/List\_of\_model\_checking\_tools
- Many are freely downloadable and modifiable for research and study purposes
- Research area with many achievements in over 30 years

## Verification Tradeoffs

#### The Model Checking Dream

#### The Model Checking Dream

## Actual Model Checking

- In order to have this computationally feasible, we need a strong assumption on the system under verification (SUV)
- I.e., it must have a *finite number of states Finite State System* (FSS)
- In this way, model checkers "simply" have to implement reachability-related algorithms on graphs
- Such finite state assumption, though strong, is applicable to many interesting systems
  - that is: many systems are actually FSSs
  - or they may be approximated as such
  - or a part of them may be approximated as such

## What Is a State?

- There are many notions of "state" in computer science
- Model checking states are *not* the ones in UML-like state diagrams
- Model checking states are similar to operational semantics states
- That is: suppose that a system is "described" by *n* variables
- Then, a state is an assignment to all *n* variables
  - given  $D_1, \ldots, D_n$  as our n variables domains, then a state is  $s \in \times_{i=1}^n D_i$

• We have two identical processes accessing to a shared resource

- in the figure below, *i*, *j* denote the two processes
- the well-known Peterson algorithm is used

- The 5 "states" in the preceding figure are actually modalities
- From a model checking point of view, they correspond to *multiple* states
- To see which are the actual states, let us model this system with the following variables:
  - $m_i$ , with i = 1, 2: the modality for process i
  - $Q_i$ , with i = 1, 2:  $Q_i$  is a boolean which holds iff process i wants to access the shared resource
  - turn: shared variable

• Thus, the resulting model checking states are the following:

- There are 25 reachable states
  - assuming state  $\langle L0, L0, f, f, 1 \rangle$  as the starting one
- All possible states are 200
  - there are 3 variables with two possible values (the 2 variables Q, plus the turn variable) and 2 variables (P) with 5 possible values, thus  $2^3 \times 5^2$  overall assignments
- The L0 modality for the first process encloses 6 (reachable) states

- There are 25 reachable states
  - assuming state  $\langle L0, L0, f, f, 1 \rangle$  as the starting one
- All possible states are 200
  - there are 3 variables with two possible values (the 2 variables Q, plus the turn variable) and 2 variables (P) with 5 possible values, thus  $2^3 \times 5^2$  overall assignments
- The L0 modality for the first process encloses 6 (reachable) states
- No need of guards on transitions!
  - guards will be needed for systems with external inputs

## From State Diagrams to Model Checking

- The UML-like state diagram is often useful to write the model
  - as we will see, this will depend on the model checker *input language*
- It is the model checker task to extract the global (reachable) graph as seen before
- And then analyze it

## Is Model Checking Important?

- ESA, NASA e IEC require most of their project to be model checked
- Important companies have dedicated laboratories for Model Checking
  - hardware: Intel, IBM, SUN, NVIDIA
  - software: IBM, SUN, Microsoft
- Many universities have research groups
  - USA: MIT, CMU, Austin, Stanford...
  - very close collaboration with companies
- The 3 "inventors" of Model Checking received Touring Award in 2007:
  - E. A. Emerson, E. M. Clarke, J. Sifakis

### Model Checking Usage

# Model Checking Usage

3 steps:

- Choose the model checker M which is most suitable to the SUV  $\mathcal{S}$  (and the property  $\varphi$ )
- Describe  $\mathcal{S}$  in the input language of M
- ② Describe the property arphi
- Invoke the model checker and wait for the answer
  - $\mathsf{OK} \Rightarrow \mathcal{S} \models \varphi$
  - FAIL  $\Rightarrow$  counterexample
    - correct the error (it may happen that  ${\mathcal S}$  or  $\varphi$  must be corrected instead...) and go back to step 3
  - OutOfMem or OutOfTime
    - adjust system parameters (or the description of S)

# Model Checking Usage

- Not actually to verify programs with "standard" input and outputs
  - input is known in advance, e.g. in sorting; standalone computation
  - for such systems, testing can be complemented with theorem proving (or with manual proof derivation)
  - of course, budget must be taken into account
- Most used for *reactive systems* 
  - always executing: monitoring (warns if something bad happens) or controlling (avoids that something bad happens)

# Model Checking: Pro and Cons

#### Pro

- Same guarantees of proof checking
- But requiring less "mathematics" and "computer science" knowledge

#### Cons

- Computational Complexity
  - causing "OutOfMem" and "OutOfTime": *State Explosion Problem*
- You check a model of the system, not the actual system
  - though in some cases models can be automatically extracted from the system

- With some semplification, all Model Checking algorithms are essentially like this:
  - Extract, from the description of the SUV S, the transition relation of S
  - Output the reachable states (reachability)
  - ${ig 0}\,$  Check if arphi holds in all reachable states
- All steps may be computationally heavy, but let us focus on the reachability
  - see mutual exclusion example
- If S is described by n (binary) variables, then the number of reachable states is O(2<sup>n</sup>)

- Such complexity cannot be avoided in the most general case
- Theoretically speaking, (LTL) Model Checking is P-SPACE complete
  - CTL Model Checking is in P, but as we will see this does not make things better
- There are different model checking algorithms, depending on the "type" of  ${\cal S}$ 
  - each checker has its "preferred" SUVs

There are 3 categories:

Explicit

• Implicit (symbolic)

- Explicit
  - each reachable state is separately stored
  - very good for communication protocols
- Implicit (symbolic)

- Explicit
  - each reachable state is separately stored
  - very good for communication protocols
- Implicit (symbolic)
  - dedicated data structures are used to represent sets of reachable states
  - very good for digital hardware
- SAT-based

- Explicit
  - each reachable state is separately stored
  - very good for communication protocols
- Implicit (symbolic)
  - dedicated data structures are used to represent sets of reachable states
  - very good for digital hardware
- SAT-based
  - many problems may be rewritten as SAT, but in model checking this works pretty well also in practice
  - software model checking

- Explicit
  - each reachable state is separately stored
  - very good for communication protocols
- Implicit (symbolic)
  - dedicated data structures are used to represent sets of reachable states
  - very good for digital hardware
- SAT-based
  - many problems may be rewritten as SAT, but in model checking this works pretty well also in practice
  - software model checking
- Proof checker ibridations
  - not completely automatic, but better than proof checkers
## Model Checking-Related Problems

- Controllers generators
  - particular case for the program synthesizer seen in the beginning
  - controllers are software modules which sends digital commands to some physical device
  - in some cases, they may be built automatically, using algorithms similar to those of Model Checking
- Probabilistic Model Checking
  - verification of stochastic processes
- Stochastic Model Checking
  - verification outcome is correct with high probability

- A Kriepke structure is a 4-tuple:  $\langle S, I, R, L \rangle$
- Formulas satisfiability:  $\pi \models \varphi \mathbf{U} \psi$  iff  $\exists j \in \mathbb{N} \ \forall 0 \le i < j\pi(i) \models \varphi \land \pi(j) \models \psi$
- $\mu$ -calcolus, e.g.:  $R(x) = \mu Z[I(x) \lor \exists x'[N(x',x) \land Z(x')]]$
- Algorithms on graphs, hash tables, OBDDs...

## ...and Practice

- We will examine the most important model checkers, also considering the source code
  - often very well written
  - in order to delay state explosion as much as possible
  - good way to learn how to code
- SUVs modeling examples

## Roadmap

- O Modeling systems with the Murphi model checker
- Kripke structures and algorithms inside Murphi: Model Checking of invariants
- LTL and CTL properties
  - safety and liveness
- OTL Model Checking algorithms
- ITL Model Checking with SPIN
- OTL Model Checking with NuSMV
- Ø Bounded Model Checking with NuSMV
- O Testing (starting from April)
